**ABSTRACT**

The structure of newly synthesized biginelli product 4-(4-nitrophenyl)-2-oxo-7-phenyl-2,3,4,5,6,7-hexahydro-1H-pyrrolo[2,3-d]pyrimidine-5-carboxylic acid (4) of 5-oxo-1-phenylpyrrolidine-3-carboxylic acid has been confirmed with the help of various spectral techniques like UV, FT-IR,  $^1\text{H}$ ,  $^{13}\text{C}$  NMR and mass spectroscopy. All quantum chemical calculations such as polarizability, hyperpolarizabilities, NBO, NLO, heat capacity, entropy and enthalpy change have been carried out at level of density functional theory (DFT) with B3LYP function using 6-31G(d,p) basis atomic set. The value of total first static hyperpolarizability ( $\beta_{tot}$ ) has been found to be  $20.5468 \times 10^{-30}$  esu, indicating that the title molecule could be an attractive future NLO material. All the possible transitions have been computed by NBO analysis and correlated with the electronic transitions. MESP plot has been derived and electrophilic and nucleophilic regions have been identified with the help of this plot. HOMO and LUMO energy values and the difference between the two has been calculated along with the computation of electronegativity and electrophilicity indices.

**Keywords:** Natural Bond Orbital (NBO), thermodynamic properties, non linear optical (NLO), molecular electrostatic potential (MESP) and atom in molecule (AIM).

## INTRODUCTION

As per literature, most of the compounds containing heterocyclic moiety are very active against several microorganism, and synthesis of such compounds have been dragging the eyes of chemist from a long time (John et al. 2004). Many heterocyclic compounds with pyrrolidine ring system, have been reported to exhibit an outstanding range of biological activities and the replacement of hydrogens of afore mentioned ring system by diversified substituents may lead to the various type of fruitful pharmacologically active compounds (Alan et al. 2003). A vast range of pharmacological activities such as anticonvulsant (Jolanta et al. 2003, Barbara 2005), antimicrobial (Lokhande et al. 2003, Mary et al. 2006, Donas et al. 2006), anti- HIV-1 (Shinichi et al. 2004) and antitumor (Xun et al. 2006) have been reported for compounds bearing pyrrolidine moiety in their skeletal

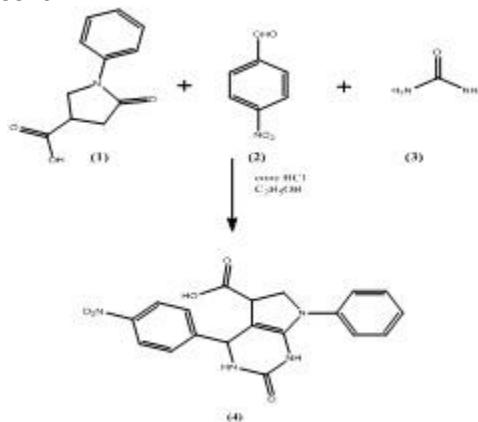

structure. Pyrrolidine derivatives also play an important role as inhibitors like ketoamide-based cathepsin K inhibitors (Barrett et al. 2006), human melanocortin-4 receptor agonists (Tran et al. 2007) and malic enzyme inhibitors (John et al. 2006). In this paper, the structure of synthesized compound 4 has been illustrated through different type of spectroscopic methods and a complete comparison has been made between the experimental and calculated data (obtained through DFT) of the compound 4. For DFT studies, it is important to choose a basis set which is well able to approximate the actual wave functions to provide chemically meaningful results. The shape of atomic orbitals gets distorted in molecule formation (polarization) and orbitals are influenced by other nuclei. To describe molecules with lone pairs, anions, transition states and excited states (loosely held e<sup>-</sup>) diffuse basis sets can be useful, therefore the DFT calculation results including mulliken atomic charges, mesp, nlo, electronic absorption spectra, nbo, thermodynamic properties, local reactivity descriptors and global reactivity descriptors have been drawn using density functional theory (DFT) method with B3LYP function using 6-31g (d,p) basis atomic set. Distribution of density of electrons in various bonding and anti-bonding orbitals have been elicited by NBO analysis.

## MATERIALS AND METHOD

NMR spectra of the compound 4 have been recorded on a Bruker 300 MHz instrument using TMS as internal reference and DMSO-d<sub>6</sub> as a solvent. Abbreviations for singlet, doublet, triplet and multiplet are quoted as s, d, t and m respectively. KBr pellet has been used for recording IR spectrum on a Perkin-Elmer Fourier transform infrared spectrophotometer. DMSO has been used as a solvent for obtaining Ultraviolet spectrum, in the region 200-500 nm on UV-visible Double-Beam Spectrophotometer (systronic-2203) instrument. The HRMS of compound 4 has been recorded on a TOF MS ES- mass spectrometer. Thin-layer chromatography (TLCs) and an iodine chamber (to develop TLCs) have been used to check the progress of reaction. Synthesis of 5-oxo-1-phenylpyrrolidine-3-carboxylic acid (1) has been done by the reported method (Paytash et al. 1950).

### Procedure for synthesis of 4-(4-nitrophenyl)-2-oxo-7-phenyl-2, 3, 4, 5, 6, 7-hexahydro-1H-pyrrolo [2,3-d] pyrimidine-5-carboxylic acid (4)

A mixture of 5-oxo-1-phenylpyrrolidine-3-carboxylic acid (1) (0.005 mol), 4-nitrobenzaldehyde (2) (0.005 mol), urea (3) (0.005 mol) and ethanol (15 mL) was refluxed under strong acidic condition (conc. HCl) for ~19 hrs at 100-110 °C. The reaction mixture was concentrated and kept overnight. Yellowish low melting solid was separated. The resulting yellowish oily product was purified by column chromatography using ethyl acetate-hexane (9.5:0.5 v/v). (Scheme 1) Yield: 41; Rf value: 0.43 [Hexane: Ethyl acetate] (8.0:2.0 v/v) as mobile phase; IR (KBr)  $\nu_{\text{max}}$ : 2850 (=CH stretching); 2981.95 (-CH stretching), 1730.15 (C=O stretching); 3360 (-NH stretching); 3480 (-OH stretching); 1307.74(-C-N stretching); 1128.36(-C-O stretching), <sup>1</sup>H NMR (DMSO-d<sub>6</sub>):  $\delta$  (ppm) = 6.20-8.3 (m, 9H, phenyl ring), 2.5-2.8 (d, 2H, CH<sub>2</sub> in pyrrolidine ring), 3.9-4.1 (m, 1H in pyrrolidine), 5.816 (s, 2H, NH), 5.44 (s, 1H in pyrimidone ring), 11(hydroxyl proton of carboxylic acid), <sup>13</sup>C NMR (DMSO-d<sub>6</sub>):  $\delta$ =59.19, 50.23, 119.86, 123-129, 139.47, 172.04, 150.74, 158-156; m/z: 380.3540.

**Scheme 1. Synthesis of 4-(4-nitrophenyl)-2-oxo-7-phenyl-2,3,4,5,6,7-hexahydro-1H-pyrrolo[2,3-d] pyrimidine-5-carboxylic acid (compound 4).**

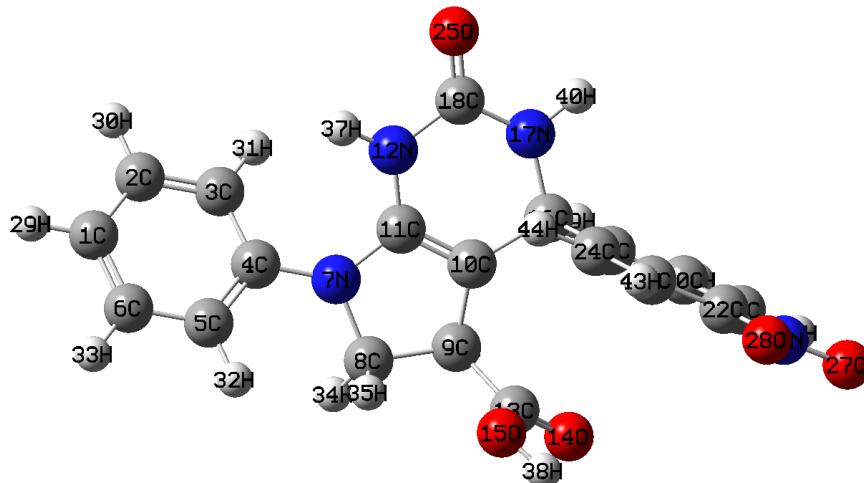

## Computational Details

The quantum chemical results of compound 4 for theoretical and experimental consistency, have been obtained by DFT with B3LYP/6-31G(d,p) (Becke 1993, Becke 1988, Lee 1988), 6-31G(d,p) basis set has been used due to the polarization of atomic orbitals during the formation of molecular orbitals with Gaussian 09 package (Schlegel 1982). Calculated IR and UV spectra of compound 4 have been plotted by using GaussView05 program. Gauge Induced atomic orbital (GIAO) method has been implemented for getting NMR chemical shifts of the compound 4 (Wolinski et al. 1990). The Frontier orbital values have been obtained by imposing time dependent density functional theory (TD-DFT) at B3LYP/6-31-G(d,p) level with the implementation of IEFPCM model and DMSO as a solvent (Cossi et al. 2001, Adamo et al. 2000). Intramolecular interactions, ring critical points, bond critical paths, ring critical point to bond critical paths and ring critical point attractor path have been obtained by AIM approach (Bader et al. 2000).

## RESULTS AND DISCUSSION

### Molecular geometry

Calculated optimized parameters like bond lengths, bond angles and dihedral angles of compound 4 have been compared with the experimental one (Table 1). All the essential experimental structural parameters have been taken from the similar systems for which the crystal structures have been solved. Figure 1 shows all the atoms present in the compound 4.

**Figure 1.** Optimized structure of compound 4.

The pure single bond character has been confirmed by comparing the calculated distance between C8-C9 (1.5541) with experimental distance between C8-C9 (1.525). The shortest bond of the compound 4 is O15-H38 (0.9723 Å). All C-C bond length and C-H bond length of rings are in the range of 1.3-1.6 Å and 1.08-1.1 Å respectively. The variations observed in the bond angles are due to the electro negativity of the central atom, lone pair of electrons and the conjugation of the double bonds.

### $^1\text{H}$ and $^{13}\text{C}$ NMR spectra

$^1\text{H}$  and  $^{13}\text{C}$  NMR spectra (experimental and theoretical) of compound 4 has been presented in Table 2. The correlation graphs of experimental and calculated  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra have been shown in Fig. 2(a) & 2(b) respectively. The linear equations followed by correlation graphs are  $y = 1.018x - 0.853$  for  $^1\text{H}$  NMR and  $y = 0.950 x + 0.298$  for  $^{13}\text{C}$  NMR. Where 'y' and 'x' are the experimental and the calculated chemical shifts respectively. Solvent used for recording the NMR spectra was DMSO-d<sub>6</sub>. Good agreement between the obtained experimental values and calculated values has been visualized from the correlation values ( $R^2 = 0.996$  using B3LYP for  $^1\text{H}$  NMR and  $R^2 = 0.991$  using B3LYP for  $^{13}\text{C}$  NMR).

**Electronic absorption**

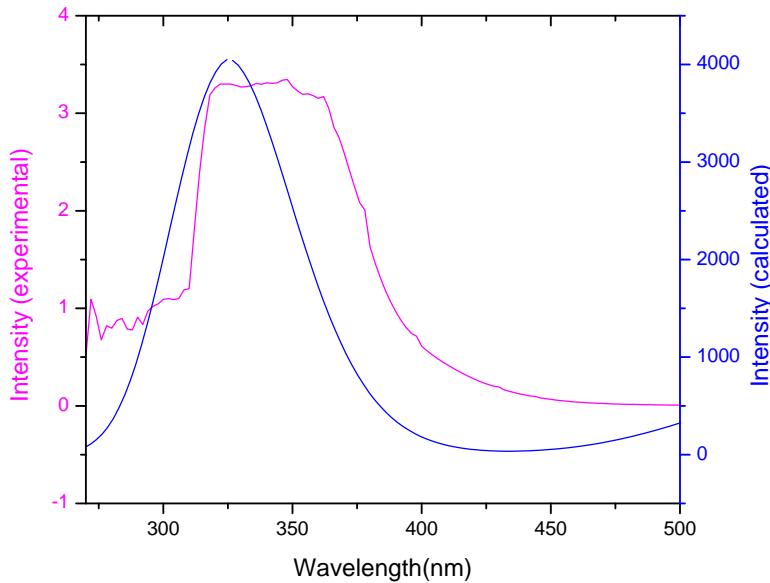

The UV-Visible spectrum of compound 4 has been studied by TD-DFT method using the previously mentioned DFT method in section 3. The percentage contribution of probable transitions, corresponding absorption wavelengths along with simulated UV data, oscillator strength (f) and vertical excitation energies have been texted in Table 2 and compared with experimental results. An intense electronic transition at 311.03 nm with an oscillator strength f = 0.1481 in DMSO has been anticipated which has been found to be very close to the experimental ( $\lambda_{\text{exp.}} = 318$  nm in DMSO). Figure 3 shows the experimental and calculated spectra of compound 4, and the corresponding transitions from HOMO to LUMO+2 with 44.17%, HOMO-2 to LUMO with 33% and HOMO-5 to LUMO with 17.18% contribution have been texted in the table 3 and shown in the figure 4. These transitions happened due to  $n \rightarrow \pi^*$  and  $\pi \rightarrow \pi^*$  transition.

**Figure 2 (a) and (b).** Correlation graph between experimental and calculated <sup>1</sup>HNMR chemical shifts (a) and between experimental and calculated <sup>13</sup>CNMR chemical shifts (b) using B3LYP 6-31G (d, p).

**Table 3.** Experimental and theoretical absorption wavelength  $\lambda_{\max}$  (nm), excitation energies E (eV) of compound 4 using B3LYP functional and 631-G/(d,p) basis set.

S. No	Electronic transitions (Molecular orbital involved)	Energy (in eV)	Calculated $\lambda_{\max}$ (in nm) B3LYP	Oscillatory strength (f)	Percentage contribution of probable transition B3LYP	Observed $\lambda_{\max}$ (in nm)
1	97→100 (H-2→L)	3.9264	315.77	0.1323	33.02%	
2	99→102 (H→L+2)	3.9863	311.03	0.1481	44.17%	318
3	94→100 (H-5→L)	4.4452	278.92	0.3284	17.18%

### Vibrational Assignment

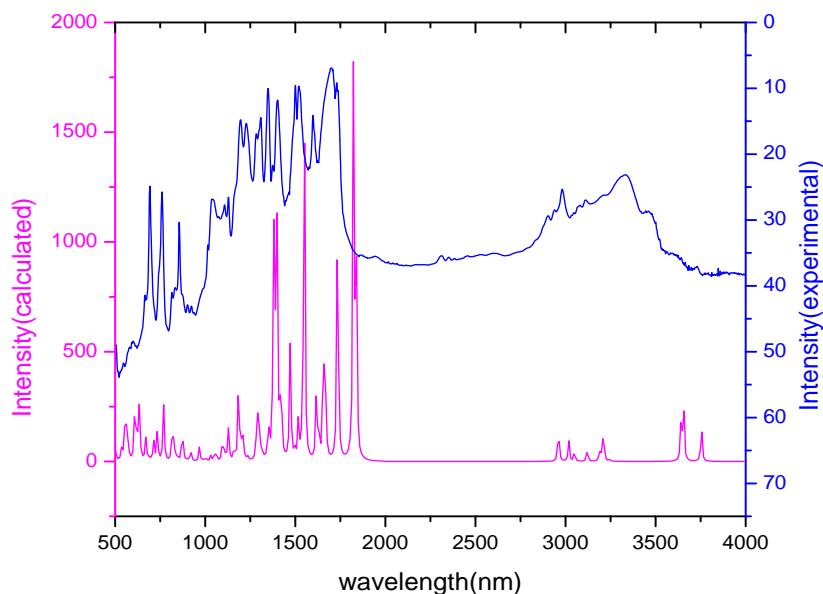

The vibrational data of novel 4-(4-nitrophenyl)-2-oxo-7-phenyl-2,3,4,5,6,7-hexahydro-1*H*-pyrrolo[2,3-*d*]pyrimidine-5-carboxylic acid (**4**) shows the presence of 44 atoms which belong to C1 point group possessing. One can look of the Figure 5 to compare the experimental and simulated vibrational spectra. The potential energy distribution (PED) and, the calculated and experimental frequencies of the compound **4** have been arranged in the supplementary Table 4.

**OH vibrations**

The reported range for has been found to lie in the region 3600-3200 cm<sup>-1</sup> (Colthup et al. 1990, Sathyanarayana 2004). In the experimental FT-IR spectrum, the OH stretching vibration has been observed at 3500cm<sup>-1</sup> and found to be in good agreement with the calculated value at 3754cm<sup>-1</sup>.

**C-H vibration**

In general most of IR frequency at 3085 cm<sup>-1</sup> has been shown by hetero aromatic compounds due to asymmetric C-H stretching (Mekala et al. 2016). The C-H stretching vibrations band of compound 4 have been observed at 2981 cm<sup>-1</sup> and calculated band at 3185 cm<sup>-1</sup>.

**Figure 5. Experimental and calculated IR spectra of compound 4.**

**C-C vibrations**

The C-C IR vibrations obtained through DFT method have been found at diverse values like 1031, 1052, 1122, 1128, 1201, 1348, 1531 and 1632 cm<sup>-1</sup> as similar to the reported values at 1043, 1303, 1443, 1470, 1533 and 1601cm<sup>-1</sup> (Roja et al. 2011). However observed values of C-C stretching vibrations are at 1037, 1107, 1128, 1195, 1226, 1307, 1348, 1402 and 1500 cm<sup>-1</sup> respectively. Hence the synthesis of compound 4 was confirmed both theoretically and experimentally.

**C=O and C-O vibrations**

The compound 4 possesses two carbonyl groups (C18=O25, C13=O14). The stretching vibrations of these carbonyl carbons have been observed at 1710 and 1730 cm<sup>-1</sup> while the calculated vibrations of these carbonyl carbons have been found at 1824 and 1839 cm<sup>-1</sup> in theoretical IR spectrum. The reported C=O stretching vibration is at 1703cm<sup>-1</sup> (Harayama et al. 2004).

**CH<sub>2</sub> vibrations**

The FT-IR values of CH<sub>2</sub> vibrations, found at 2960, 3017, 3049, 3185 and 3192 cm<sup>-1</sup> have shown similarity to the reported values appeared in the regions 3020-2855 cm<sup>-1</sup> (Roeges 1994, Silverstein et al. 2003). On the other hand experimentally obtained FT-IR spectrum has shown values of CH<sub>2</sub> stretching vibrations between 2981- 3100 cm<sup>-1</sup>.

**NH vibrations**

It has been found that the secondary amide group was present in compound 4. The stretching vibrations of both –NH– groups have been observed at 3350 and 3460 cm<sup>-1</sup> while these values have been calculated at 3639 and 3654 cm<sup>-1</sup>. The reported stretching vibration of –NH– in a secondary amide group has been found to be observed at 3500-3100 cm<sup>-1</sup>.

### Molecular electrostatic potential (MESP)

Hydrogen–bonding interactions, electron density and centre for electrophilic, and nucleophilic attacks have been explained through MESP plot (Prabavathi et al. 2014, Prasad et al. 2013). The molecular electrostatic potential contour surface of compound 4 has been visualized by the Figure 6. Different colors indicate the diverse values of the electrostatic potential at the surface in increasing order as follows (Grossman 2013, Singh et al. 2013, Zaater et al. 2016):

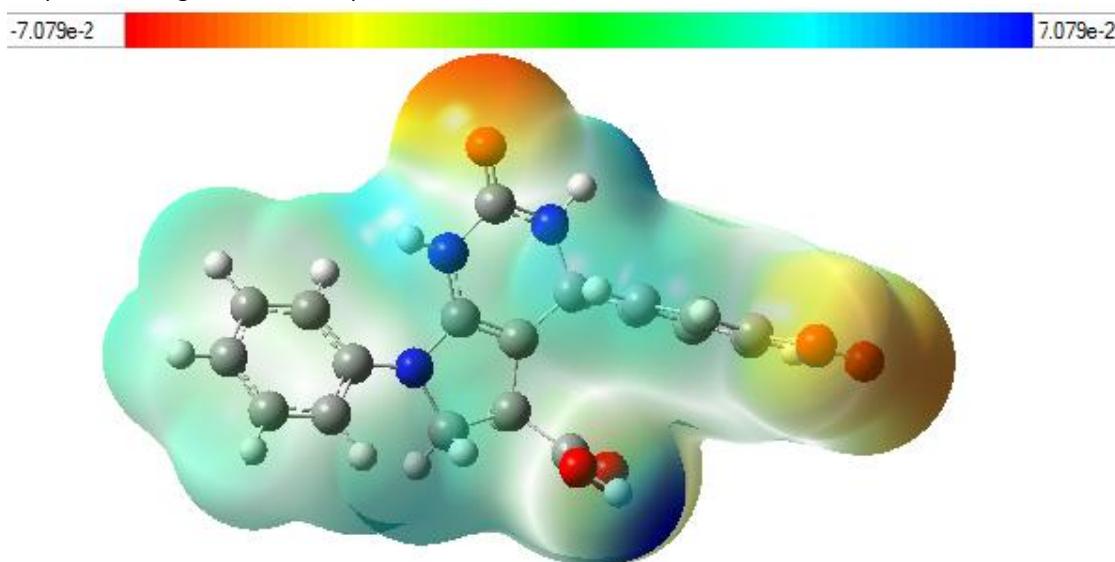

Red < yellow < green < light blue < blue

→→→→→→→→→→→→→→→→

Figure 6 represented that the region around O25, O27 and O28 occupied more negative electrostatic potential with MEP value around -7.079 a.u than the region around C18, C22, C11, C13 and N26 with a MEP value of +7.079 a.u. From these values the following outputs have been obtained:

The most preferred regions for electrophilic attacks →O25, O27 and O28.

The most preferred regions for nucleophilic attacks → C22, C11, C13 and N26.

**Figure 6. 3D plot of the molecular electrostatic potential of the compound 4.**

### Natural bond orbital analysis

The Gaussian09 package at the B3LYP/6-31 G (d,p) basis set has been put upon for NBO analysis (Glendening et al. 1998). Occupancy of donor and acceptor bonds, lone pair energy, hyper conjugative interactions in molecular systems, interactions between electron donors and electron acceptors and the stabilization energy values have been obtained from Natural bond orbital (NBO) analysis. It has been found that more intense interactions between electron donors and electron acceptors are those which possess larger stabilization energy value. The extent of conjugation is also proportional to stabilization energy value. The following equation (2) shows the correlation between stabilization energy E (2), occupancy of donor orbital (qi), diagonal elements of donor (i) and acceptor (j) level bonds (Ei and Ej respectively) and off diagonal NBO Fock matrix element (Fij) (Reed et al. 1988) in accordance with the second order Fock matrix in NBO analysis .

$$E(2) = \Delta E_{ij} = q_i \frac{(F_{ij})^2}{(E_j - E_i)} \quad (1)$$

The NBO analysis has been texted in Table 5. From this table it has been visualized that the some of the high energy charge transfers are from bonding  $\pi$  (C1-C6) to antibonding  $\pi^*$  (C2-C3) and (C4-C5) and with stabilization energy of 22.85 and 19.39 kcal mol<sup>-1</sup> respectively, presenting the presence of conjugated system,

and intramolecular charge transfers from  $\pi$  (C2-C3) to  $\pi^*$  (C1-C6) and (C4-C5) with stabilization energy of 17.43 and 21.01 kcal mol<sup>-1</sup> respectively. A charge transfer has also been noticed from  $\pi$  (C4-C5) to  $\pi^*(C1-C6)$  with stabilization energy of 21.35 kcal mol<sup>-1</sup>, showing aromatic character inside the system.

Few transitions such as from nonbonding orbital of O15 and N12 to  $\pi^*(C13-O14)$  and (C10-C11) put forth very high stabilization energy of 47.18 and 40.75 kcal mol<sup>-1</sup> respectively. In molecule 4 charge transfer from  $\pi$  of O14 to  $\sigma^*(C13-C15)$  with stabilization energy of 34.5 kcal mol<sup>-1</sup>, from nonbonding orbital of O25 to  $\sigma^*$  orbitals of (N12-C18) and (N17-C18) with stabilization of 27.09 and 25.46 kcal mol<sup>-1</sup> respectively and from nonbonding orbital of O27 to  $\sigma^*$  orbital of (N26-N28) with stabilization of 19.27 kcal mol<sup>-1</sup> have also been extracted from calculated data. All these charge transfers have been originated due to corresponding delocalization of electrons inside the system.

**Table 5. Second order perturbation theory analysis of Fock matrix in NBO basis of the compound 4.**

**Non -linear optical analysis**

NLO shell outs major advantages (as well as some limitations) to some very important applications in sensors, commercial lasers, environmental monitoring, telecommunications, manufacturing, medicine and materials processing, in scientific and the military. NLO has generated high-resolution spectroscopy, enforced micromachining, offered new materials analysis tools, and high-capacity telecommunications. The high quality fiber optics systems that have been used to empower the internet, the technology used in advanced medical devices, in controlling water and air pollution, and in characterization of new materials have been offered by NLO (Elsa 2013). Organic aromatic systems possess polarization due to presence of conjugated  $\pi$ -bonds and the donor and acceptor groups which give rise to a high nonlinear optical coefficient. The following equations (2-4) have been applied to calculate the first hyperpolarizability  $\beta_{tot}$ , average polarizability  $\alpha_{tot}$  and total dipole moment  $\mu$  of the studied compound (4) employing the x,y,z components (Kleinman 1962 ).

$$\mu_{tot} = (\mu_x^2 + \mu_y^2 + \mu_z^2)^{1/2} \quad 2$$

$$\alpha_{tot} = \frac{1}{3}(\alpha_{xx} + \alpha_{yy} + \alpha_{zz}) \quad 3$$

$$\langle \beta \rangle = \left[ (\beta_{xxx} + \beta_{xyy} + \beta_{xzz})^2 + (\beta_{yyy} + \beta_{yzz} + \beta_{yxx})^2 + (\beta_{zzz} + \beta_{zxz} + \beta_{zyy})^2 \right]^{1/2} \quad 4$$

4

The corresponding data of electronic dipole moment  $\mu$  ( $i = x, y, z$ ), first hyperpolarizability and polarizability have been texted in Table 6. The calculated dipole moment, polarizability  $\alpha_{tot}$  and first hyper polarizability for the title compound 4 are equal to 5.93 D,  $0.9063 \times 10^{-24}$  esu and  $20.5468 \times 10^{-30}$  esu respectively for B3LYP level.

**Table 6. Dipole moment ( $\mu_{tot}$ ), polarizability ( $\alpha_{tot}$ ), anisotropy of polarizability ( $\Delta\alpha$ ) and static hyperpolarizability ( $\beta_{tot}$ ) calculated at DFT/B3LYP/6-31G (d,p) level of theory.**

Dipole Moment		Static Hyperpolarizability	
$\mu_x$	-5.3864	$\beta_{xxx}$	1903.14
$\mu_y$	-2.2788	$\beta_{xyy}$	140.02

$\alpha_{tot}$	$0.906342 \times 10^{-24}$		

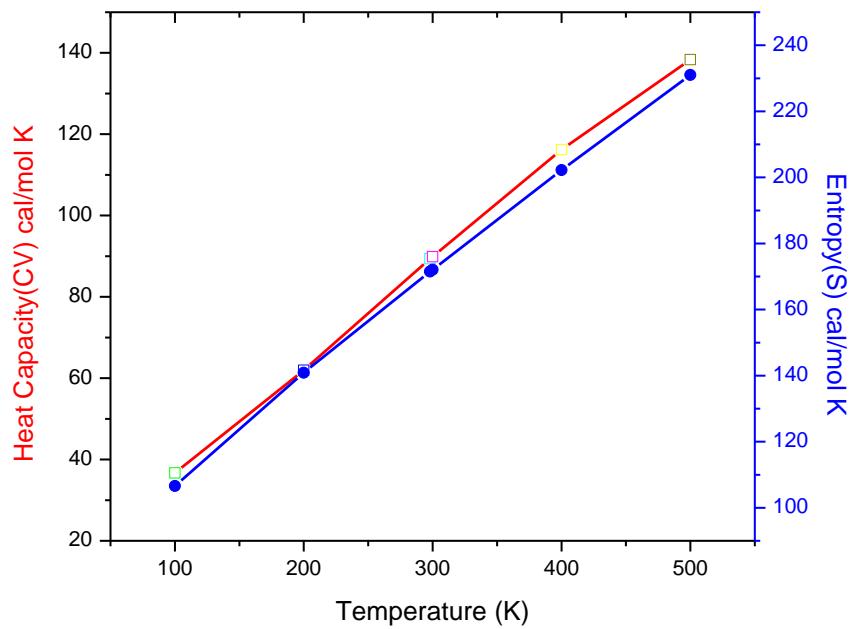

**Thermo dynamical analysis**

Thermo dynamical properties play momentous role in the accompaniment of numerous chemical and physical phenomena. In the present study, the DFT-B3LYP/6-31G(d,p) method has been applied to extort rotational constants and zero point vibrational energy at standard temperature (298.15 K) along with two statistical thermodynamic functions, entropy (S) and heat capacity (CV) at different temperatures (from 100 to 500 K), texted in the table 7(a) & 7(b) for the title compound 4.

The correlative graph of these thermodynamic properties and temperatures (T) has been shown in Figure 7. As the temperature increases from 100 to 500 K, the molecular vibrational intensities also increases that leads to the enhancement of heat capacity and entropy with the temperature. The fitting factors ( $R^2$ ) for the heat capacity, entropy and temperatures have been found to be 0.998 and 0.99 respectively and can be used to find out other thermodynamic energies (gibbs free energy) and to estimate the feasibility of chemical reactions. All thermodynamic calculations have been performed in gas phase.

**Table 7(a). Calculated thermodynamic parameters of compound 4 at standard temperature 298.15 K.**

Parameters	B3LYP6-31G(d,p)

**Reactivity descriptors****Global Reactivity Descriptors**

The computation of reactivity descriptors such as electronegativity ( $\chi$ ), global hardness ( $\eta$ ), chemical potential ( $\mu$ ), electrophilicity index ( $\omega$ ) and global softness ( $S$ ) have put forth an appreciable approach to predict global reactivity trends. In molecular systems, Koopman's theorem has been fundamentally imposed to ascertain site selectivity and chemical reactivity (Prasad et al. 2013, Arivazhagan et al. 2015, Soliman et al. 2015, Sethi et al. 2015). The aforementioned reactivity descriptors have been calculated using following equations. [(5)-(12)] and texted in Table 8.

$$IP = -\varepsilon_{HOMO} \quad (5)$$

$$EA = -\varepsilon_{LUMO} \quad (6)$$

$$\chi = -\frac{1}{2}(\varepsilon_{LUMO} + \varepsilon_{HOMO}) \quad (7)$$

$$\mu = -\frac{1}{2}(I + A) \quad (8)$$

$$\eta = \frac{1}{2}(I - A) \quad (9)$$

$$\omega = \frac{\mu^2}{2\eta} \quad (10)$$

$$S = \frac{1}{2}\eta \quad (11)$$

$$\Delta N = -\mu / \eta \quad (12)$$

**Table 8. Calculated frontier molecular orbitals ( $\varepsilon_{LUMO}$ ,  $\varepsilon_{HOMO}$ ), band gap ( $\varepsilon_{LUMO}-\varepsilon_{HOMO}$ ), ionization potential (IP), electron affinity (EA), electronegativity ( $\chi$ ), global hardness( $\eta$ ), chemical potential ( $\mu$ ), global electrophilicity index ( $\omega$ ), global softness ( $S$ ) and additional electronic charge ( $\Delta N_{max}$ ) of product 4 using B3LYP/6-31G(d,p) basis set.**

	$\varepsilon_H$	$\varepsilon_L$	$\varepsilon_H - \varepsilon_L$	IP	EA	$\chi$	$\eta$	$\mu$	$\omega$	S	$\Delta N_{max}$
P	-0.1877	-0.09563	-0.0921	0.1877	0.0956	0.1416	0.0460	-0.1417	0.2181	10.86	3.0784

**Local reactivity descriptors**

Condensed Fukui Function ( $f_k$ ) is a descriptor of the reactivity of an atom in a molecule. The condensed value around each atomic site indicates the atomic contribution of molecule. The  $f_k$  values are defined as

$$f_K^+ = [q(N+1) - q(N)] \text{ for nucleophilic attack} \quad (13)$$

$$f_K^- = [q(N) - q(N-1)] \text{ for electrophilic attack} \quad (14)$$

$$f_K^0 = \frac{1}{2} [q(N+1) - q(N-1)] \text{ for radical attack} \quad (15)$$

Where, N, N-1, N+1 represent total electrons those are present in neutral, anionic and cationic states of molecule respectively.

The following equations define the local reactivity descriptors for site k

$$s_K^+ = Sf_K^+, s_K^- = Sf_K^-, s_K^0 = Sf_K^0 \quad (16)$$

$$\omega_K^+ = \omega f_K^+, \omega_K^- = \omega f_K^-, \omega_K^0 = \omega f_K^0 \quad (17)$$

Where +, -, 0 signs show attack of nucleophile, electrophile and radical respectively. The more prone site for nucleophilic or electrophilic attack than other atomic sites can be obtained through visualizing the values of all these local reactivity descriptors, higher values of these local reactivity descriptors indicate that these sites are liable to nucleophilic or electrophilic attack. Fukui functions ( $f_k^+$ ,  $f_k^-$ ), local electrophilicity indices ( $\omega k^+$ ,  $\omega k^-$ ) and local softnesses ( $sk^+$ ,  $sk^-$ ) (Parr et al. 1999, Chattaraj et al. 2007) for selected atomic sites of molecule have been texted in Table 9. The comparatively hiked values of local reactivity descriptors ( $f_k^+$ ,  $sk^+$ ,  $\omega k^+$ ) observed at N26, C10, C5, C1 and C3 show that these sites are more liable to nucleophilic attack, where as the relatively high values of these descriptors ( $f_k^-$ ,  $sk^-$ ,  $\omega k^-$ ) at C22, O27, O28, O25 and C24 suggest that these site are more prone for attack of electrophiles. These explorations have furnished enough information about the molecule for further studies.

**Table 9. Hirshfeld population analysis: Fukui functions ( $f_k^+$ ,  $f_k^-$ ), local softnesses ( $sk^+$ ,  $sk^-$ ) in eV, local electrophilicity indices ( $\omega k^+$ ,  $\omega k^-$ ) in eV for selected atomic sites of compound 4.**

**AIM approach**

In order to achieve diverse type of intramolecular interaction like strong, medium, weak H-bonds and their covalent, partially covalent and electrostatic nature, values of Laplacian of electron density ( $\nabla^2 \rho(\text{BCP})$ ) and total electron density at bond critical point ( $H_{\text{BCP}}$ ) should be known which can be obtained through implementation of AIM program to the compound 4 (Rozas et al. 2000). Figure 8 shows the molecular graph of compound 4 and, in table 10 parameters (geometrical and topological) for bonds of interacting atom have been texted.

Strong H-bonds  $\nabla^2 \rho(\text{BCP}) < 0$  and  $H_{\text{BCP}} < 0$

Medium H-bonds  $\nabla^2 \rho(\text{BCP}) > 0$  and  $H_{\text{BCP}} < 0$

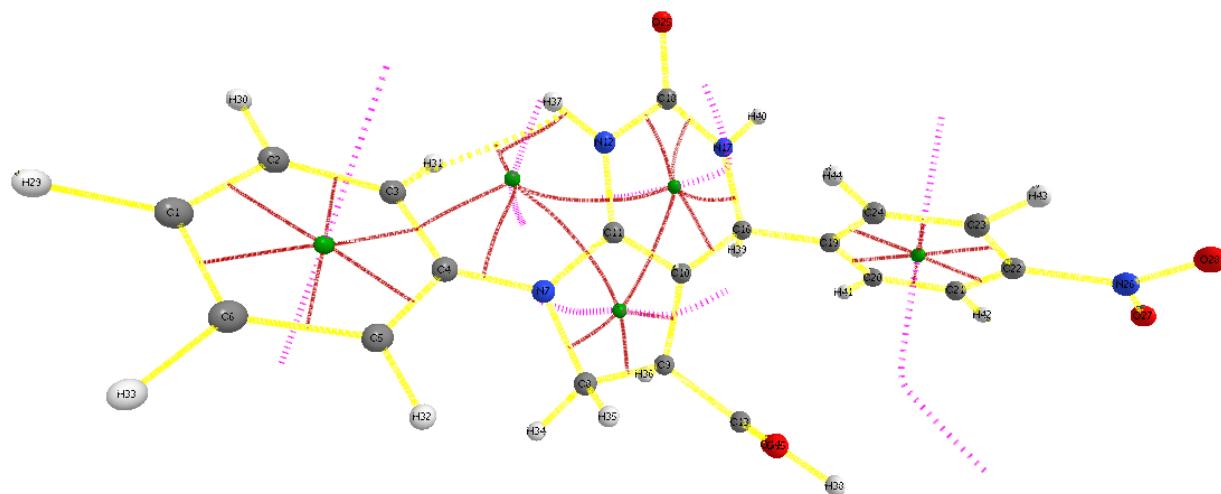

Weak H-bonds  $\nabla^2 \rho(\text{BCP}) > 0$  and  $H_{\text{BCP}} > 0$

As the ( $\rho_{\text{BCP}}$ ) parameter and  $H_{\text{BCP}}$  parameter have been found to be greater than zero and less than zero respectively. Consequently N12-H37.....H31 is a medium interaction. From the AIM calculations it has been found that the total energy of intramolecular interactions is 0.511914 kcal/mol and the ellipticity value of this intramolecular hydrogen bond is +0.050208. The  $\epsilon$  is related to  $\lambda_1$  and  $\lambda_2$ , which corresponds to the eigen values of Hessian and connected by a relationship:  $\epsilon = (\lambda_1 / \lambda_2) - 1$ . This value of ellipticity indicates the electron delocalization in the aromatic ring as ellipticity ( $\epsilon$ ) monitors the  $\pi$ -character of bond (Matta et al. 2007).

**Table 10. Topological parameters for intramolecular interaction in compound 4 electron density ( $\rho_{\text{BCP}}$ ), laplacian of electron density ( $\nabla^2 \rho_{\text{BCP}}$ ), electron kinetic energy density ( $G_{\text{BCP}}$ ), electron potential energy density ( $V_{\text{BCP}}$ ), total electron energy density ( $H_{\text{BCP}}$ ), hydrogen bond energy ( $E_{\text{HB}}$ ) at bond critical point (BCP).**

Interactions	$\rho_{\text{BCP}}$	$\nabla^2 \rho_{\text{BCP}}$	$G_{\text{BCP}}$	$V_{\text{BCP}}$	$H_{\text{BCP}}$	$E_{\text{HB}}$
N12-H37.....H31	+0.34294	-1.84318	0.05111	-0.56303	-0.381553	0.511914

$\rho_{\text{BCP}}, \nabla^2 \rho_{\text{BCP}}, G_{\text{BCP}}, V_{\text{BCP}}, H_{\text{BCP}}$  in a.u. and  $E_{\text{HB}}$  in (kcal/mol)

**Figure 8. Molecular graph of the compound 4 using AIM program at B3LYP/6-31G (d,p) level ring critical points (small green sphere), bond critical paths (yellow lines), ring critical point to bond critical paths (red lines) and ring critical point attractor path (purple lines).**

## CONCLUSION

The newly synthesized 4-(4-nitrophenyl)-2-oxo-7-phenyl-2,3,4,5,6,7-hexahydro-1H-pyrrolo[2,3-d]pyrimidine-5-carboxylic acid (4) has been characterized and quantum chemical calculations have been done with help of B3LYP/6-31G(d,p) basis set. Vibrational assignments of the wavenumbers have been carried out with the help of potential energy distribution approach. MESP technique has been used for assaying the centre of electrophilic and nucleophilic attacks, electron density, hydrogen-bonding interactions, structural and symmetry properties of compound 4. The confirmation of the hyper conjugative interactions and, inter and intra molecular interactions of the molecular system compound 4 have been analyzed by NBO analysis. The biological activity depends on the charge transfer, which is expected from calculated HOMO and LUMO energies, derived from second order perturbation theory. There was an excellent agreement with experimental data of chemical shift values as provided by GIAO NMR. The NLO analysis including hyperpolarizability, polarizability values and, total and partial dipole moment showed that the molecule is a claimant NLO material. The thermo dynamical analysis clearly indicated that the increase of the temperature led to increase in the thermo dynamical parameters like heat capacity and entropy. The results of the AIM approach (Ellipticity and intramolecular hydrogen bond interactions) depicted  $\pi$ -character of bonds in the aromatic ring and medium hydrogen bonds.

## ACKNOWLEDGEMENTS

The authors convey their thanks to the Head, Department of Chemistry, Lucknow University, Lucknow, for providing laboratory facilities for spectral analysis and central facility for computational research and they are also thankful to the director of Kanpur IIT, Kanpur, for providing mass spectral data.
