ABSTRACT

This work was carried out to study the genetic diversity in parental lines of hybrid rice (O. sativa L). The genetic diversity between two parents has been proposed as a possible predictor of F1 performance and heterosis in rice. Genetic diversity is studied by using molecular markers. The role of genetic markers in genetic enhancement is considered in the evaluation of genetic diversity. The more polymorphic the trait the greater its potential value to germplasm management. Genetic diversity in 48 lines was studied. Genomic DNA isolation was carried out. SSR's are capable of detecting a high level of polymorphism among inbreed lines (Liu and Wu; 1998). Therefore identified SSR primers were selected to carry out this work. Polymorphism detection was conducted using 58 primer pairs on each chromosome. Allele diversity was observed among the selected lines. Dendrogram was observed for five different clusters. The average dissimilarity between first and second cluster was 60%, between second and third was 62.42%, between third and fourth was 59.8%, between fourth and fifth was 52.66%, between fifth and first was 50.66%. The data obtained in this study could be utilized in further studies for development of hybrids to exploit heterosis. Key words: Oryza sativa L, SSR marker, Heterosis, Polymorphism, Genetic diversity and Hybrid.

INTRODUCTION

Hybrid rice is a proven and successful technology for rice production, having contributed significantly toward improving food security, raising rice productivity and farmer's income, and providing more employment opportunities over the past three decades. After China, India is a second country to commercially exploit this technology to benefit of the farming community. Hybrid rice is rice that been created by crossing two different parental strains. Such crosses generally result in an F1 generation that is more robust than either of the parental strains. The enhanced yield performance of F1 generation is referred to as "hybrid vigour" or "heterosis". The hybrid vigour may result in superior agronomic qualities such as higher yield, stronger resistance to disease, more efficient use of a soil nutrients, and better weed control. Hybrid vigour and other superior qualities arising from crossing genetically different plants have been well known and used by traditional crop breeders for decades.

J. Biol. Chem. Research

The level of genetic diversity between two parents has been proposed as a possible predictor of F1 performance and heterosis in rice. This propositions stems from studies by Lin Yuan (1980) Yuan and Cheng (1986). So in order to identify the gene of interest it is necessary to study genetic diversity in hybrid rice. Genetic diversity is studied by using molecular markers like RAPD and SSR which are PCR based markers. The role of genetic markers in genetic enhancement is considered in the evaluation of genetic diversity. Traits that serve as genetic markers are by definition polymorphic. The more polymorphic the trait, the greater its potential value to germplasm management.

The emphasis of this report would be on DNA based molecular techniques and how they can apply in assessing the genetic diversity of parental lines of hybrid rice (*O. sativa L*). For an optimum exploitation of heterosis, parents should be derived from genetically divergent pools, commonly referred to as heterotic groups. Characterisation of genetic variation within the breeding lines could be crucial for effective exploitation of genetic resources for crop improvement programs. The assessment of genetic diversity of a set of parental lines would help to identify the most diverse lines and such lines could be tested for development of hybrids to exploit heterosis. Microsatellites are often multi-allelic because of high mutation rate. Therefore SSR markers were used in this study for theassessment of genetic diversity in 48 parental lines of hybrid rice. The present study has been designed with the objectives, to PCR amplify a set of parental line of hybrid rice using the identified SSR markers and to assay the genetic diversity among these lines utilizing SSR marker polymorphism data.

MATERIALS AND METHODS

Collection of samples

48 parental lines of hybrid rice were collected from Directorate of Rice Research (DRR), Hyderabad for the present study (Table no. 1.1). All 48 rice varieties seeds were soaked in Petri plates in moistened blotting paper at room temperature for proper germination then the leaf samples were collected from 7-10 days rice seedlings after seed germination for genomic DNA extraction.

Preparation of stock solutions

1M Tris HCl (PH 8.0), 0.5M EDTA, 5M NaCl, Bromophenol Blue, 10X TBE.

DNA isolation

Genomic DNA from the leaf samples was isolated using the procedure of Zheng *et al.* (1995) with some modifications. The quantity of extracted genomic DNA from all 48 lines was estimated by agarose gel electrophoresis method.

SSR Markers

SSRs are capable of detecting a high level of polymorphism among inbreed lines. Therefore we have selected SSR primers for this work. For 1-9 and 11-12 chromosome 5 primers each and for 10th chromosome 3 primers were used. In all 58 primers were used for 12 sets of chromosome (Table no. 1.4).

PCR and Electroporesis

Master mix for PCR (10µl): D.W. 3µl, Assay buffer 10X) 1µl, dNTPs0.5µl, Primer forward (20µm) 1µl, Primer reverse (20µm) 1µl, Taq polymerase (0.5U/µl) 0.5µl, DNA sample 3µl. The PCR tubes were then setup in programmable thermal cycler for DNA amplification. The temperature specifications for the denaturation of DNA strands, Annealing of primers and extension steps in SSR were as follows. (Table no. 1.2) PCR amplified products were resolved in 3% agarose gel in 0.5X TBE buffer at 100V for 3.5 hrs in Hoefer super submarine Electrophoresis unit containing 0.5 X TBE buffer solution. Prior to loading, 1/6th volume of gel loading dye (40% sucrose; 0.25% bromophenol blue) was added to the PCR amplified products and ensured proper mixing. The sizes of amplified fragments were determined by comparing with 100 bp ladder (MBI Fermentas). The gels were stained in Ethidium Bromide (10mg/ml) and placed over the UV-transilluminator and documented using ALPHA IMAGER gel documentation system (M/s Alpha innotech) for documentation (Figure 1.1).

Data Analysis

Qualitative multistage traits that depict an array of characters were converted into binary characters (Sneath and Sokal, 1973) based on the variations present. Only the clear and unambiguous bands of SSR markers were scored.

Markers were scored for the presence and absence of the corresponding band among the genotypes. The score 1 and 0 indicates the presence and absence of the bands respectively. A data matrix comprising of '1' and '0' were formed depending upon the character and this data matrix was subjected to further analysis using DARWIN 5.0 analysis software.

RESULTS AND DISCUSSION

The present study aimed to study genetic diversity of parental lines of hybrid rice was carried out using 58 different HRM primers. In rice 12 chromosomes are present for each chromosome HRM primers were tested. The radial type of dendrogram was obtained using DARWIN analysis software version 5.0 (Figure 1.2) also the mathematical values were calculated by factorial analysis (Table no. 1.3). The average dissimilarities between clusters were calculated. In 1st cluster 3 green super lines, 1restorer line, 1maintainer line (IR 79156B) was exists. The maintainer line showed 66% similarity with GSRT-103, whereas restorer line RPHR -1005 showed 63% similarity with GSRT – 103 the average similarity of first cluster was 51%.

In 2nd cluster has further subdivided into 3 sub cluster. Only 2 genotypes were exists in 2 (a) cluster that were green super line GSRT-107 and 1 check variety SABHAGI DHAN showed 51% similarity. The average similarity of second cluster was 76% whereas 2nd (b) cluster has 4 genotype.TJ-18, NWGR-3045, IR-58025B, TJ-52. 2 restorer lines and 1 green super line GSRT -106 showed 49% similarity. While check variety JAYA showed 55% similarity with GSRT-106. The average similarity of this cluster was 49%. In 2nd (c) cluster 2 tropical japonica lines, 1 maintainer line IR58025B existed showed 64% similarity with each other. The average similarity of this line IR58025B existed showed 64% similarity with each other. The average similarity of this cluster was 64%. In cluster 3 (a) 2 maintainer lines, 1 restorer line DR 714-2R were exists showed 49% similarity. The average similarity of cluster was 50%. Cluster 3 (b) contains 4 genotypes. 2 restorer line showed 48% similarity. The average similarity of this cluster was 62%. In cluster 3 (c) 3 genotypes were exists. 2 restorer lines and 1 green super line GSRT-104 showed 77% similarity with RPHR-1004. The average similarity of cluster was 67%. In cluster 3 (d) 5 genotypes were exists.2 maintainer line,1 green super line GSRT-102 showed 53% similarity with APMS 6B. Tropical japonica line TJ-11 and IBL 51 showed 39% similarity. TJ-11 had 61% similarity with maintainer line IR 68897B. Average similarity of this cluster was 63%.

Only tropical japonica lines were present in cluster 4. The average similarity between them was 57%. The average similarity of this cluster was 57%.

In cluster 5 (a) 5 genotypes were exists. 2 maintainer lines showed 64% similarity. 2 restorer lines were exists ICRD 16-4-2 and IR 40750R which showed 54% similarity. The average similarity of this cluster was 49%.

In 5 (b) cluster 8 genotypes were exists. 2 green super lines showed 68% similarity. 1tropical japonica line was exists which showed 41% similarity with DRR10B. The average similarity of this cluster was 52%.

Table No. 1.4. PCR conditions kept.

Sr.No	Steps	Temperature	Time
1.	Initial denaturation	94 ^o C	5 min.
2.	Denaturation	94 ^o C	30 sec.
3.	Annealing	55 ⁰ C	30 sec.
4.	Extension	72º C	1 min.
5.	Final extension	72 ⁰ C	7 min.
6.	Cooling	4 ^o C	α

CONCLUSION

Average dissimilarity between all clusters was observed as follows.

The average dissimilarity between 1^{st} and 2^{nd} cluster was 60%

The average dissimilarity between 2^{nd} and 3^{rd} cluster was 62.42%.

The average dissimilarity between 3rd and 4th cluster was 59.8%

The average dissimilarity between 4^{th} and 5^{th} cluster was 52.66%

The average dissimilarity between 5^{th} and 1^{st} cluster was 50.66%.

ACKNOWLEDGEMENTS

It gives us immense pleasure and privilege to express our profound regards and deep sense of gratitude to Dr. A. S. Hari Prasad (Principal Scientist), HYBRID RICE section, Directorate of Rice Research, (currently IIRR) Rajendranagar, Hyderabad for his valuable guidance throughout research work. The author stake the opportunity to express sincere thanks to Dr. M. Sheshu Madhav (Senior Scientist), Department of Biotechnology, Directorate of Rice Research for providing all the facilities to carry out work.

The authors are very much thankful to Dr. M. R. Patil (Chairman Royal Education Society) for providing precious support during the research work.

We express our sincere thanks to Dr. N.S. Zulpe (Principal COCSIT, Latur) for their firm support during the research work.
